A New Species and Host Association Biology of Neotropical
Compsobraconoides Quicke (Hymenoptera: Braconidae)

Abstract.—The new species Compsobraconoides cinnamomi Fortier and Nishida is described from Costa Rica. Specimens were obtained from galls on lower branches of Cinnamomum cinnamomifolium (Kunth) Kosterm that were caused by Camptocheirus Lacordaire (Coleoptera: Curculionidae). Compsobraconoides larvae were observed feeding on Camptocheirus larvae in galls.

Resumen.—La nueva especie Compsobraconoides cinnamomi Fortier and Nishida es descrita para Costa Rica. Especímenes fueron obtenidos de agallas en ramas de árboles de Cinnamomum cinnamomifolium (Kunth) Kosterm. Las agallas son inducidas por una especie de Camptocheirus Lacordaire (Coleoptera: Curculionidae). Larvas de C. cinnamoni fueron observadas alimentándose de larvas de Camptocheirus sp. en agallas.

Of the cosmopolitan braconid subfamily Braconinae, which is composed of about 200 genera and 5000 species worldwide (Quicke 1988, Quicke and Sharkey 1989), Compsobraconoides Quicke is a moderately large, principally neotropical genus, occurring from the southern U.S. to South America including the Caribbean. The genus was erected by Quicke (Quicke and Sharkey 1989). A new species has been described by Quicke (Quicke and Sharkey 1989), as well as the new combination Compsobraconoides albispina (Cameron), formerly Bracon albispina Cameron.

Braconine females usually oviposit through substrate containing the host, usually attacking late larval instars. Hosts usually are concealed within living plant tissue, such as tree bark, stems of annual and biennial plants, galls, and seed heads. Some braconines attack casebearing hosts (Shaw and Huddleston 1991). Most braconines are idiobiont ectoparasitoids, and eggs are generally laid on the host’s body, although first instar larvae are able to travel short distances to locate their hosts if necessary (Shaw and Huddleston 1991).

Prior to this study, one host record existed for an unidentified Compsobraconoides species from three species of Azteca ants (Dolichoderinae) colonizing domatia of Cordia nodosa Lam. (Boraginaceae) in Peru (Yu & Quicke 1997). This study represents the first host record for a described Compsobraconoides species, and the first association of a Compsobraconoides species with Coleoptera. Both host associations involve hosts in swollen plant tissue. Since Azteca ants do not occur in the United States, while Compsobraconoides does, it was obvious that Compsobraconoides must have other hosts.

MATERIALS AND METHODS

Galls induced by Camptocheirus Lacordaire sp. were collected in August and September, 2000, January, February, and June to August, 2001, and May, June, September, and November, 2002. Collections were made on the campus of the University...
sity of Costa Rica (elevation: 1150 m.) in San Pedro, San José, Costa Rica. The habitat on which the university campus is located was considered to be a moist premontane tropical forest (Holdridge 1967). However, it is now a large urbanized part of San José. The surrounding area is therefore highly altered. A few coffee plantations still remain in the area. Identification of Camptocheirus was made by C. H. Lyal, The Natural History Museum, London.

Stems with mature galls were collected from lower branches (approximately three to five m. from the ground) of three Cinnamomum cinnamomifolium (Kunth) Kosterm (Lauraceae) trees (height: ca. 15 m, tree base diameter ca. 77 to 184 cm) and were carried back to the entomological laboratory of the university (average room temp. 23 to 24 °C). The collected galls (about 120) were split in half longitudinally and observed. The galls were resealed when presented in any stage of the parasitoid (Figs. 1-4), and these were reared in transparent plastic bags.

RESULTS AND DISCUSSION

Two relatively small Compsobracoonoides cinnamomi larvae (apparently late first or early second instar) were found attached to an immobile mature Camptocheirus larva in a gall that was collected on October 29, 2002. On November 2, 2002, only one larva was observed attached to the host larva and it measured ca. 5.5 mm (Fig. 2). The other larva did not survive. Six days later, on November 4, 2002, the Compsobracoonoides larva appeared to finish feeding on the host, i.e. the larva was not attached to the host larva (Fig. 3). On November 5, 2002, the parasitoid larva began to spin the cocoon in the gall chamber. At
this time, the larva was approximately 6.5 mm long. The larva pupated within a few days; however the pupa did not survive until adult formation. From another rearing record, the pupal stage took approximately 10 days. A more or less recently developed pupa (Fig. 4) was collected on October 29, 2002; and the Compsobraconoides cinnamomi adult was flying in the plastic bag on November 6, 2002.

Evidently the adult chews through the hard gall wall in order to emerge from the gall. The gall wall was approximately 4-5 mm thick, fibrous, and relatively hard. A few dead adult Compsobraconoides cinnamomi individuals were observed in the gall. The time between the adult emergence and the emergence from the gall may possibly take more than a week since the host adult, Camptocheirus sp., takes five to fourteen days to tunnel.

We estimate that approximately 10% of total (120) galls collected contained Compsobraconoides cinnamomi. However, fourteen mature galls were collected on May 10, 2003 of which six were parasitized by C. cinnamomi.

**Compsobraconoides cinnamomi** Fortier and Nishida, new species
(Figs 5-11)

*Female.*—Body color: nearly uniformly honey yellow, head black except for yellow clypeus, labrum, mandibles; mandibular tips black; yellow rim at dorsal eye margin; black antennae except yellow base of first flagellomere; front and middle legs with yellow coxae, trochanters, trochantelli, and tarsi, dark brown or black femora, tibiae brown or black except yellow at basal ends, hind coxae, trochanters and trochantelli honey yellow, hind femora honey yellow, hind tibiae, tarsi dark brown or black; wings dusky, stigma medium brown with white tip at basal margin, veins medium brown basally becoming lighter apically, fore-wing vein r-m unpigmented. Body length: 5.3-7.5 mm. Head: malar space shorter than basal

width of mandible and about 0.25 length of eye; oral opening height 0.9 of width, width twice length of malar space, face shiny rugulose, three ridges, two extending from antennae to clypeus, one medial (Fig. 5); 39-43 flagellomeres, all slightly longer than wide (Fig. 6), ocelli small, diameter of postero-lateral ocellus less than ocell-ocular space (Fig. 5); frons nitid, sulcus running from point between anterior bases of antennae to anterior of anterior ocellus, bifurcating into two sulci that each terminate at points ventro-lateral of posterior ocelli; vertex, temples, and occiput nitid; palpus not swollen; mandibular tips overlapping when closed. Mesosoma:
pronotum nitid, a sulcus on either side of antero-medial ridge running ventro-lateral-ly, terminating at points in antero-lateral areas of pronotum, directly anterior to tegulae, posterior margin on each side of pronotum with a single notch about midway between where pronotum touches tegula and postero-ventral extremity of pronotum; scutum, scutellum nitid, nota-uli unsculptured, transverse scrobiculate sulcus dividing scutum and scutellum; mesopleuron nitid, broad sulcus running from point near pronotal notch to dorsal-most point of mesopleuron, anterior edge of sulcus carinate; metapleuron, propodeum smooth-punctate with long, silky white setae, median longitudinal carina in apical half or third (Fig. 7). Legs: tarsal claws without pectination but with some-what pointed basal lobe (Fig. 8), inner spur of hind tibia about 0.5 length of hind basitarsus, hind coxa smooth-punctate with long, silky white setae (Fig. 9). Wings (Fig. 11): second submarginal cell of fore-wing elongate; 3RSa about 0.65 of 2M; vein r 0.4 length of 3RSa; 1cu-a contiguous with 1M; hindwing RS recurved, not reaching wing margin apically, thus mar-ginal cell open, narrowest apically; 1RSa, 1RSb, r absent, thus RS runs basally to join R at costal cell, R1 ending just before wing apex; sub-basal cell small, M+CU 0.4 of M. Metasoma: all tergites nitid, translu-cent, 1st metasomal tergite quadrate, lat-eral flanges extending along lengths of sides of tergite, over spiracles, raised rounded structure in apical half of tergite, increasingly raised over surface of tergite...
apically, highest point just basal of median point of apex (Fig. 10), 2nd metasomal tergite articulating with first by anteriorly projecting medial process that inserts under apical edge of rounded structure of first tergite, wide medial rounded notch in medial area of apex of 2nd tergite, 3rd tergite evenly convex, 4th and 5th tergites evenly, but more acutely convex, both with wide, shallow tranverse sulcus, 8th abdominal tergite with dark-brown cerci, cerci with long dark setae, setae longer than cercus, each cercus 0.06 mm. Ovipositor: about as long as metasoma, ovipositor sheath black with black setae along entire length.

Male.—Essentially as in female, except humeral plate black medially, in some tegula also black, Body length: 5.3–5.6 mm.

Holotype female.—COSTA RICA: San Jose, San Pedro, UCR campus, 1150 m., 30/V/2002-21/X/2002, ex: larva Camptocheirus sp. (Coleoptera: Curculionidae), from gall on Cinnamomum cinnamomifolium, K. Nishida. Deposited in USNM.

Paratypes.—COSTA RICA: two females, three males, same data as holotype. One male deposited in USNM. Two females and two males deposited in INBIO.

Distribution.—Known only from type locality in Costa Rica.

Biology.—Idiobiont ectoparasitoid of gall forming Camptocheirus sp. (Coleoptera: Curculionidae) on Cinnamomum cinnamomifolium.

Host distribution.—Costa Rica; recorded from Central Valley of Heredia (Suarez, 1992) and San José province.

Plant distribution.—Cinnamomum cinnamomifolium, formerly known as Phoebe cinnamomifolia, commonly occurs from elevations around 600 m up to about 1500 m in both the Pacific and the Atlantic slopes in Costa Rica. This plant species ranges from southern Mexico through Central America and into South America (Burger and van der Werff 1990).

Comments.—This species differs from Compsobraconoides robustus Quicke in having a black head, yellow clypeus, labrum,
mandibles, yellow base of first flagellomere, front and middle legs with yellow trochanters (Quicke and Sharkey 1989). It differs from Compsobraconoides albispina (Cameron) in having the second metasomal suture strongly arched medially, the head uniformly black, fore- and mid-tibiae yellow at basal ends rather than uniformly piceous, and hind femora entirely honey yellow rather than the apical 0.1 piceous (D. Quicke, personal communication). The host (Camptocheirus sp.) is a new species currently being worked on by C. H. Lyal and K. Nishida.

Etymology.—Named after host plant on which this species was found feeding on Camptocheirus.

ACKNOWLEDGMENTS

We thank Donald Quicke for help in revising the manuscript, and Scott R. Shaw for coordinating communication between the authors, and forwarding the specimens. We also thank Nancy Galvin for assistance with the scanning electron microscope, David Neeley for use of the Leica 9.5 stereomicroscope with drawing tube used for the wing drawings, and Peter Bernhardt for assistance and advice.
